Problem 1. Draw a flowchart from which the following compensator can be programmed if the sampling interval is 0.1 seconds.

$$G_c(z) = \frac{1899z^2 - 3761z + 1861}{z^2 - 1.908z + 0.9075}$$

$$G_c(z) = \frac{X(z)}{E(z)} = \frac{1899z^2 - 3761z + 1861}{z^2 - 1.908z + 0.9075}$$

Cross-multiply and obtain

$$(z^2 - 1.908z + 0.9075)X(z) = (1899z^2 - 3761z + 1861)E(z)$$

Solve for the highest power of z operating on the output, $X(z)$,

$$z^2X(z) = (1899z^2 - 3761z + 1861)E(z) - (-1.908z + 0.9075)X(z)$$

Solving for $X(z)$ on the left-hand side,

$$X(z) = (1899 - 3761z^{-1} + 1861z^{-2})E(z) - (-1.908z^{-1} + 0.9075z^{-2})X(z)$$

$$1899$$

Delay T

$C(z)$

DAC

$G(s)$
